For instance, if a prey animal such as a vole were to have a light and a dark phenotype, a predator might recognize the more common phenotype as food. So if the light voles are more common, foxes may be keeping a closer eye out for light phenotypic voles, recognising them as good prey. This would reduce the light causing alleles due to increased predation and the dark genotypes would increase their proportion of the population until this scenario is reversed. This cycle continues perpetually. \n\nHowever, this is unlikely to be strictly yearly as it usually takes more time than a year for an entire populations allele frequencies to change enough to make a large enough difference to alter fitness. \n\nMore likely on a *year to year* basis, the population is experiencing fluctuating selection where al...
